

What players earn should not end with one game.

Roxin is a shared value and settlement layer for game economies. ROXIN is the vehicle that carries portable value between participating games while each developer keeps control of its own economy.

One portable value layer. Many local game expressions.

The token is infrastructure, not the product story. The product is dependable value portability between games.

This document describes the current pre-seed product and token design. Governance rights, distribution terms, implementation details, and legal rights remain subject to final documentation.

01 / THESIS

Game economies create value. Most of it cannot travel.

Players invest time, skill, creativity, and money inside individual games. When they move on, almost all economic progress resets. Studios also rebuild payments, balances, reward logic, and partnership infrastructure in isolation.

For players	For studios	For ecosystems
Value is trapped inside one title. Leaving usually means starting from zero.	Each game carries the burden of payments, balance, fraud controls, and partner integrations.	Cross-game partnerships remain bespoke, slow, and difficult to measure.

The product thesis

Games do not need one universal currency. They need a shared layer that can recognize portable value, settle it between participating games, and let each studio decide how that value appears and behaves locally.

Interoperability at the boundary. Sovereignty inside each game.

Why this can become a platform

- Every additional game can add utility for existing players.
- Every accepted value route can reduce the cost of the next partnership.
- Settlement history can make value movement measurable and auditable.

02 / PRODUCT

A translation layer, not a replacement economy.

Each game keeps its own currency, balance rules, visual identity, local utility, and economic design. Roxin handles only the portable portion that participating studios agree to recognize.

1 · Earn locally A player earns or owns eligible value through play, purchase, creation, or another studio-approved action.	2 · Carry through ROXIN The platform validates eligibility and route policy. ROXIN carries the portable value record through settlement.	3 · Express locally The destination grants its own local form: credit, item access, crafting power, or another permitted utility.
---	--	---

The critical boundary

ROXIN is not automatically spendable everywhere. A destination studio chooses whether to accept a route, how much to accept, what the incoming value becomes, and under which limits.

ROXIN carries value across the network. Each game decides what that value means locally.

What the shared layer should provide

Game SDK Create eligible events, request translations, and grant local utility.	Policy controls Configure routes, caps, counterparties, settlement rules, and emergency controls.	Settlement ledger Record source, destination, rule version, fees, status, and reconciliation evidence.
---	---	--

03 / TOKEN

ROXIN is the network's portable-value and governance asset.

The token has two jobs at this stage: carry value between participating game economies and align early backers with the network they are helping fund and govern.

TOKEN	MAX SUPPLY	STAGE
ROXIN	200,000,000,000	Pre-seed

Portable value ROXIN is the common vehicle used to move agreed value from one game context to another.	Governance At pre-seed, early investors receive ROXIN to participate in the project's governance as that governance is activated.	Alignment Vesting keeps team, investors, and growth allocations exposed to the same long-term outcome rather than immediate distribution.
--	---	---

Governance is not corporate equity

Holding ROXIN is intended to provide governance participation in the Roxin network. It does not by itself represent shares in a legal company, ownership of company assets, or a guaranteed financial return unless separate legal documents explicitly grant those rights.

The token should gain importance because the network becomes useful — not the other way around.

04 / TOKEN ALLOCATION

Fixed supply. Explicit allocation. Time-based release.

The 200 billion ROXIN maximum supply is allocated across four purposes. Vesting limits early concentration and aligns distribution with continued participation and network growth.

20%	20%	15%	45%
TEAM & DEVELOPMENT 40B ROXIN	INVESTORS 40B ROXIN	MARKETING & EXPANSION 30B ROXIN	LIQUIDITY & CIRCULATION 90B ROXIN

Allocation	Share	Vesting / release	Primary purpose
Team & development	20% / 40B	24 months · linear	Contributor continuity and Roxin development-related spending.
Investors	20% / 40B	24 months · linear	Pre-seed and future investor allocation; long-term governance alignment.
Marketing & expansion	15% / 30B	12 months · linear	Partnerships, studio/user acquisition, ecosystem and market expansion.
Liquidity & circulation	45% / 90B	No fixed vesting stated	Liquidity, settlement circulation, and network activity as demand develops.

Linear vesting means the allocated balance unlocks progressively across the stated period rather than becoming available at once. This litepaper does not define an additional cliff; final distribution contracts should make start dates, claim mechanics, and any transfer restrictions explicit.

Token vesting is separate from any founder-equity vesting defined in company-level agreements.

Team allocation principle

The team allocation exists to keep the people building Roxin financially able to continue and to fund Roxin-related development and operating needs. It is not intended as an unrestricted short-term extraction pool.

Govern the network. Do not govern the games.

ROXIN governance should coordinate network-level rules while preserving the original product boundary: each participating studio remains the economic authority inside its own game.

Network governance can cover Treasury and allocation policy, network-level parameters, major protocol changes, and other shared rules as governance is progressively activated.	Studios continue to control Accepted value sources, conversion rules, local utility, budgets, caps, player eligibility, pauses, reversals, and economic balance.
---	--

A game can join the network without surrendering its economy.

Pre-seed governance principle

At pre-seed, the founding team remains responsible for execution. Token governance should expand only where decision rights are clear, measurable, and safe to decentralize. Governance participation should not create ambiguity about operational responsibility.

Controls required before broader governance

- Published proposal and voting rules.
- Clear scope: which decisions token holders can and cannot change.
- Transparent treasury and token-allocation reporting.
- Emergency controls for settlement or security incidents.
- Protection against concentration, rushed proposals, and governance capture.

Start with one valuable route, not a universal network.

The first proof is a narrow partnership between a small number of games where portable value creates a measurable benefit and cannot destabilize either economy.

Phase 1 · Prove	Phase 2 · Productize	Phase 3 · Expand
Two compatible games. One value type. Strict caps. Manual review and reconciliation. Measure real use.	Package repeated work into SDKs, policy controls, reporting, and automated settlement operations.	Add trusted partners and routes, then broaden governance and network participation carefully.

What must be true

- Studios will accept external value under bounded rules.
- Players understand and use portability.
- A route improves activation, retention, or revenue enough to justify its cost.
- Integration and settlement are repeatable.

Failure conditions to watch

Economic contamination	Speculation before utility	Governance misalignment
External value distorts progression, pricing, or competitive fairness.	Token demand becomes the story before real game utility is proven.	Voting power or incentives push decisions away from network health.

Prove that portable value changes player behavior before scaling the financial layer.

07 / ROADMAP

Build utility first. Scale the token around evidence.

The roadmap is sequenced around the largest uncertainties: developer acceptance, player behavior, safe settlement, and repeatability.

Now · Pre-seed	Next · Controlled pilot	Then · Repeatability
Complete distribution and vesting controls; continue studio discovery; define one bounded cross-game value route.	Ship a minimal SDK, policy service, ledger, admin controls, and reconciliation workflow for two partner games.	Standardize onboarding, route templates, reliability controls, reporting, and governance processes as real usage grows.

Known risks

- Token speculation can outpace product utility.
- External value can damage game balance if routes are not bounded.
- Governance can be captured or become too slow for operational decisions.
- Liquidity and market price can be volatile and should not be treated as a product KPI.
- Token distribution and governance rights may face different legal treatment across jurisdictions.

The next milestone is evidence: one route, two games, real players, measurable value movement.

Document status

Litepaper v0.2 · September 2026. Prepared as a concise pre-seed explanation of Roxin's product thesis, token role, allocation, vesting, validation strategy, and known risks.

Informational only. This document does not guarantee token value, liquidity, investment return, legal classification, or a particular governance outcome. Corporate equity, if any, must be granted through separate legal documentation. Token terms should be reviewed for the jurisdictions in which distribution occurs.
